Dynamic-MRI assessment of the temporal and spatial distribution of glucose and oxygen in resting muscle. The purpose of this work was to study the relationship between the spatial distribution of metabolite concentration and glucose

consumption in human muscle. In vivo dynamic-MRI experiments were performed in leg muscle at 9.4 T on a 3D spoiled gradient-recalled acquisition in a steady-state (SPGR) sequence. Water, lactate and O2 maps were calculated from the spin-lattice relaxation time T1, and the spin-spin relaxation

time T2. The D-glucose maps were calculated from the exchange time t1, and the transit time tau. The spatial distribution of D-glucose consumption was studied by continuous infusion of 3D-SPGR with serial measurements in muscle (n = 6) and muscle/perfusion (n = 4) experiments and by 3D-

SPGR imaging on external fixation (n = 8). Water, lactate and oxygen concentrations decreased with increasing depth in resting muscle. The concentration of lactate and water exhibited similar trends, while D-glucose concentration decreased more with decreasing depth.

Lactate, oxygen and D-glucose concentration decreased rapidly in external fixation experiments compared with those in muscle experiments, while the variability increased. The current D-glucose and oxygen maps are in good agreement with the lactate concentration maps, but the two maps

are not correlated (R = 0.35 and 0.57). These results are consistent with previous studies and suggest that the method has the capacity to monitor oxygenation dynamics in vivo. However, the relationship between lactate and D-glucose concentrations is complex and cannot be

described simply by use of a single perfusion factor. Since D-glucose is consumed mainly in muscle mitochondria, the lactate and D-glucose concentrations can be correlated indirectly by linking the lactate and water concentrations.[A case of true bone metastasis from clear cell renal cell

carcinoma responding to zoledronic acid]. A 67-year-old female was referred to our hospital, complaining of right hip pain. Based on bone scintigraphy, the patient was diagnosed as having metastatic bone disease. She underwent total hip arthroplasty of the right hip on admission. After the operation, we found

one metastatic bone lesion on bone scintigraphy. Histological examination of the specimen revealed clear cell renal cell carcinoma. Although bone metastases of clear cell renal

wheelchair use in patients with neurodegenerative diseases. A number of studies have documented that brain diseases are associated with changes in motor behaviour. However, little is known of the trajectory of these changes and the major factors that influence it.

To describe and quantify change over the course of disease in motor behaviour in people with a neurodegenerative disease who are using a wheelchair for mobility. A randomised cross-sectional study. People who had a diagnosis of Parkinson's disease (PD) and dementia with Lewy bodies (DLB), with or

without a related cognitive impairment, were recruited from outpatient clinics. The main outcome measures were motor-subtype classification based on the Unified Parkinson's Disease Rating Scale (UPDRS) and a domain-specific measure of motor function and disability, the FAST

(functional analysis in severe tremor). Hierarchical linear regression and latent class growth analyses were used to model change in the main outcome measures over time. In addition, the researchers undertook an in-depth qualitative analysis of the participants' narratives

about their experience of using a wheelchair. The baseline mean age of the 50 participants was 69 years, and there was an approximately 17-year gap between disease onset in those with early-stage disease and wheelchair use onset. Recruitment to the study took place across a wide range of

disease durations (2-24 years). Clinical assessments were repeated at a mean of 8 years and 6 months after wheelchair use onset. The main outcome measures indicated progressive decline in motor function and disability for most participants. The trajectories could be

characterized as follows: (i) 'Progression' – the majority of participants showed UPDRS subtype progression, demonstrating a decline in at least one motor-subtype class, along with UPDRS-III score progression, and functional decline based on FAST scores; (ii) 'Latent growth' - motor

function classes remained the same or worsened, but the rate of decline was moderated by UPDRS-III-score trajectory; (iii) 'No change' - some participants maintained the same motor-subtype classes over time; and (iv) 'Tremor-dominant' - the tremor-dominant motor phenotype was

maintained without change or deterioration. The findings indicated that motor function and disability decline was a common phenomenon in PD and DLB, especially in people with early-stage disease or those whose tremor-dominant phenotype was not sustained. The study also highlighted the

need for clinical services to
